# REMARKS ON THE UNIQUENESS FOR QUASILINEAR ELLIPTIC EQUATIONS WITH QUADRATIC GROWTH CONDITIONS 

DAVID ARCOYA, COLETTE DE COSTER, LOUIS JEANJEAN, AND KAZUNAGA TANAKA

#### Abstract

In this note we present some uniqueness and comparison results for a class of problem of the form $$
\begin{equation*} -L u=H(x, u, \nabla u)+h(x), \quad u \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega) \tag{0.1} \end{equation*}
$$ where $\Omega \subset \mathbb{R}^{N}, N \geq 2$ is a bounded domain, $L$ is a general elliptic second order linear operator with bounded coefficients and $H$ is allowed to have a critical growth in the gradient. In some cases our assumptions prove to be sharp.

## 1. Introduction

For a bounded domain $\Omega \subset \mathbb{R}^{N}(N \geq 2)$ and a function $h \in L^{p}(\Omega)$ for some $p>\frac{N}{2}$ we consider the problem

$$
\begin{equation*}
-L u=H(x, u, \nabla u)+h(x), \quad u \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega) \tag{1.1}
\end{equation*}
$$

where $L$ is a general elliptic second order linear operator and $H: \Omega \times \mathbb{R} \times \mathbb{R}^{N} \rightarrow \mathbb{R}$ is a Carathéodory function which satisfy the assumptions:
(L) There exists a family of functions $\left(a^{i j}\right)_{1 \leq i, j \leq N}$ with $a^{i j} \in L^{\infty}(\Omega) \cap W_{l o c}^{1, \infty}(\Omega)$ such that

$$
L u=\sum_{i, j} \frac{\partial}{\partial x_{j}}\left(a^{i j}(x) \frac{\partial u}{\partial x_{i}}\right)
$$

and, there exists $\eta>0$ such that, for a.e. $x \in \Omega$ and all $\xi \in \mathbb{R}^{N}$,

$$
\sum_{i, j} a^{i, j}(x) \xi_{i} \xi_{j} \geq \eta|\xi|^{2}
$$

(H1) There exists a continuous function $C_{1}: \mathbb{R}^{+} \rightarrow \mathbb{R}^{+}$and a function $b_{1} \in$ $L^{p}(\Omega)$ such that, for a.e. $x \in \Omega$, all $u \in \mathbb{R}$ and all $\xi \in \mathbb{R}^{N}$,

$$
|H(x, u, \xi)| \leq C_{1}(|u|)\left(|\xi|^{2}+b_{1}(x)\right)
$$

[^0](H2) There exists a function $b_{2} \in L_{l o c}^{N}(\Omega)$ and a continuous function $C_{2}: \mathbb{R}^{+} \times$ $\mathbb{R}^{+} \rightarrow \mathbb{R}$ such that, for a.e. $x \in \Omega$, all $u_{1}, u_{2} \in \mathbb{R}$ with $u_{1} \geq u_{2}$ and all $\xi_{1}, \xi_{2} \in \mathbb{R}^{N}$,
$$
H\left(x, u_{1}, \xi_{1}\right)-H\left(x, u_{2}, \xi_{2}\right) \leq C_{2}\left(\left|u_{1}\right|,\left|u_{2}\right|\right)\left(\left|\xi_{1}\right|+\left|\xi_{2}\right|+b_{2}(x)\right)\left|\xi_{1}-\xi_{2}\right| .
$$

As we shall see in the proof of Corollary 2.1, a sufficient condition for (H2) is that for a.e. $x \in \Omega, H(x, \cdot, \cdot) \in \mathcal{C}^{1}\left(\mathbb{R} \times \mathbb{R}^{N}\right)$ with

$$
\begin{equation*}
\frac{\partial H}{\partial u}(x, u, \xi) \leq 0, \text { a.e. } x \in \Omega, \forall u \in \mathbb{R}, \forall \xi \in \mathbb{R}^{N} \tag{1.2}
\end{equation*}
$$

and that there exists a function $b_{3} \in L_{l o c}^{N}(\Omega)$ and a continuous nondecreasing function $C: \mathbb{R}^{+} \times \mathbb{R}^{+} \rightarrow \mathbb{R}^{+}$satisfying

$$
\begin{equation*}
\left|\frac{\partial H}{\partial \xi}(x, u, \xi)\right| \leq C(|u|)\left(|\xi|+b_{3}(x)\right) \text {, a.e. } x \in \Omega, \forall u \in \mathbb{R}, \forall \xi \in \mathbb{R}^{N} \tag{1.3}
\end{equation*}
$$

Uniqueness of solution for problem (1.1) (with $L u=\Delta u$ ) has been first studied in the work [4] and after improved in [3] by requiring weaker regularity conditions on the data. The reader can also see additional uniqueness results in [5] for subcritical nonlinear term $H$ (with respect to $\xi$ ), i.e, when its growth is less than a power $|\xi|^{q}$ with $q<2$, and in the work [2] for the case that $H$ has a singularity at $u=0$.

Specifically, in [3] the uniqueness of solution for every $h$ is proved when it is assumed condition (1.3) and the following strengthening of (1.2):

$$
\frac{\partial H}{\partial u}(x, u, \xi) \leq-d_{0}<0, \text { a.e. } x \in \Omega, \forall u \in \mathbb{R}, \forall \xi \in \mathbb{R}^{N}
$$

However, in the case that it is only assumed the general hypothesis (1.2) (together with (1.3)), the authors require to the function $h$ to be sufficiently small in an appropriate sense. Furthermore, adapting the arguments of [3], the case where (1.2)-(1.3) hold and $h$ has sign can also be covered. Nevertheless, the treatment of the general case (1.2)-(1.3) with no assumptions on $h$ seems out of reach with the approach of [3, 4].

The special case of (1.1) given by

$$
\begin{equation*}
-\Delta u=d(x) u+\mu(x)|\nabla u|^{2}+h(x), \quad u \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega) \tag{1.4}
\end{equation*}
$$

is studied in [1] by an alternative approach. Indeed, if $d, h \in L^{p}(\Omega)$ for some $p>\frac{N}{2}, \mu \in L^{\infty}(\Omega)$, then it is proved that (1.4) has at most one solution as soon as $d \leq 0$. Actually this condition is also necessary since [1, Theorem 1.3] proves that (1.4) may have two solutions if $d \ngtr 0$. See also, in that direction, Theorem 2 in [13] or Theorem 1,(iv) in [16]. We also mention that a general condition which guarantees the existence of one solution to (1.4) is derived in [1]. This condition always hold when $d<0$ but also widely when $d \leq 0$. For example, we have existence of one solution whenever $\mu$ and $h$ have opposite sign.

The aim of this paper is to show that the approach of [1] can be generalized to treat, under the assumptions (L)-(H1)-(H2), equation (1.1) and thus to cover additional situations where the approach of [3, 4] is not applicable. As a counterpart of our approach we need to assume that the boundary of $\Omega$ is sufficiently smooth, namely that $\Omega$ satisfies the following condition (A) of [14, p.6].

Definition 1.1. Let $\Omega \subset \mathbb{R}^{N}$ be an open set. We say that $\Omega$ satisfies condition (A) provided there exist $r_{0}, \theta_{0}>0$ such that if $x \in \partial \Omega$ and $0<r<r_{0}$, then

$$
\text { meas } \Omega_{r} \leq\left(1-\theta_{0}\right) \text { meas } B_{r}(x)
$$

for every component $\Omega_{r}$ of $\Omega \cap B_{r}(x)$, where $B_{r}(x)$ denotes the ball of radius $r$ centered at the point $x$.

For the reader convenience, we shall prove in the Appendix (see Lemma A.1), that condition (A) holds true if $\partial \Omega$ is Lipschitz.

The main result of this paper is the following theorem.
Theorem 1.1. Assume that (L)-(H1)-(H2) hold and that $\Omega$ satisfies condition (A). Then (1.1) has at most one solution.

The proof of Theorem 1.1 is divided into two main steps. First we show that any solution of (1.1) belongs to $\mathcal{C}^{0, \alpha}(\bar{\Omega}) \cap W_{\text {loc }}^{1, N}(\Omega)$ for some $\alpha \in(0,1)$. This result is obtained combining classical regularity arguments from [11, 14] which allow to conclude that it belongs to $\mathcal{C}^{0, \alpha}(\bar{\Omega}) \cap W_{l o c}^{1, q}(\Omega)$ for some $\alpha \in(0,1)$ and some $q>2$. Here the fact that our solutions are bounded seems essential. Then a bootstrap argument of [6, 10] (see also [9]) comes into play. The key ingredient of this bootstrap is an interpolation result due to Miranda [15] which says that any element of $\mathcal{C}^{0, \alpha}(\bar{\Omega}) \cap W_{l o c}^{2, \frac{q}{2}}(\Omega)$ belongs to $W_{l o c}^{1, t}(\Omega)$ for a $t>q$. Having obtained the announced required regularity the second step consists in establishing a comparison principle. Roughly speaking, we adapt an argument from [7], based in turn on an original idea from [8] to show in Lemma [2.2 that if $u_{1}, u_{2} \in H_{0}^{1}(\Omega) \cap W_{\text {loc }}^{1, N}(\Omega) \cap \mathcal{C}(\bar{\Omega})$ are respectively a lower solution and an upper solution of (1.1), then $u_{1} \leq u_{2}$ in $\Omega$. The uniqueness then follows from this comparison principle.

As we already mentioned Theorem 1.1 is sharp for equation (1.4). More globally the condition (H2), which in essence express the fact that $u \rightarrow H(x, u, \xi)$ is a non decreasing function and $\xi \rightarrow H(x, u, \xi)$ is locally Lipschitz, appears to us as an almost necessary condition to guarantee the uniqueness.

Throughout the rest of the note we assume that $N \geq 3$. The easier case $N=2$ is left to the reader.

## 2. Uniqueness results

First we show that, when condition (A) holds, any solution of (1.1) belongs to $\mathcal{C}^{0, \alpha}(\bar{\Omega}) \cap W_{\text {loc }}^{1, q}(\Omega)$ for some $\alpha \in(0,1)$ and $q>2$. This follows directly from the following two classical regularity results.

Proposition 2.1. Assume that $\Omega$ satisfies the regularity condition (A) and that condition (L) holds. Let $u$ be a solution of

$$
-L u+a(x, u, \nabla u)=0, \quad u \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega)
$$

If there exists a constant $\mu>0$ and a function $b_{1} \in L^{p}(\Omega)$ with $p>\frac{N}{2}$ such that

$$
|a(x, u, \xi)| \leq \mu\left[|\xi|^{2}+b_{1}(x)\right], \text { a.e. } x \in \Omega, \forall u \in \mathbb{R}, \forall \xi \in \mathbb{R}^{N}
$$

then $u \in \mathcal{C}^{0, \alpha}(\bar{\Omega})$ for some $\alpha \in(0,1)$.
Proof. This result is a special case of [14, Theorem IX-2.2 p.441].
Proposition 2.2. Assume that $L$ satisfies condition (L). Let u be a solution of

$$
-L u+a(x, u, \nabla u)=0, \quad u \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega)
$$

If there exists a $\mu>0$ and a function $b_{1} \in L^{s}(\Omega)$ for some $s>1$ such that

$$
|a(x, u, \xi)| \leq \mu\left[|\xi|^{2}+b_{1}(x)\right], \text { a.e. } x \in \Omega, \forall u \in \mathbb{R}, \forall \xi \in \mathbb{R}^{N}
$$

then there exists an exponent $q>2$ such that $u \in W_{\text {loc }}^{1, q}(\Omega)$.
Proof. This result is a special case of [11, Proposition 2.1, p.145].
Clearly Propositions 2.1 and 2.2 apply to the solutions of (1.1).
The information that an arbitrary solution of (1.1) belongs to $\mathcal{C}^{0, \alpha}(\bar{\Omega}) \cap W_{l o c}^{1, q}(\Omega)$ for some $\alpha \in(0,1)$ and $q>2$ is the starting point of a bootstrap argument which relies on the following interpolation result due to C. Miranda [15].

Proposition 2.3. Let $\omega \subset \mathbb{R}^{N}$ be a bounded domain satisfying the cone property. Assume that $0 \leq \alpha<1, p \geq 1$ and let

$$
t=\frac{p(2-\alpha)-\alpha}{1-\alpha}
$$

Then any element of $\mathcal{C}^{0, \alpha}(\omega) \cap W^{2, p}(\omega)$ belongs to $W^{1, t}(\omega)$.
Proof. This result is [15, Teorema IV].
Gathering Propositions 2.1, 2.2 and 2.3 we obtain
Lemma 2.1. Assume that conditions (L) and (H1) hold and that $\Omega$ satisfies condition (A). Then any solution of (1.1) belongs to $\mathcal{C}^{0, \alpha}(\bar{\Omega}) \cap W_{\text {loc }}^{1, N}(\Omega)$ for some $\alpha \in(0,1)$.

Proof. Let $u$ be an arbitrary solution of (1.1). As $u$ is bounded, we are in position to apply Propositions 2.1 and 2.2 with $\mu=\max _{\left[-\|u\|_{\infty},\|u\|_{\infty}\right]} C_{1}(|u|)$. Then Propositions 2.1] and 2.2 implies that $u \in \mathcal{C}^{0, \alpha}(\bar{\Omega}) \cap W_{\text {loc }}^{1, q}(\Omega)$ for some $\alpha \in(0,1)$ and $q>2$. If $q \geq N$ then the proof is done, while if $q<N$ we follow a bootstrap argument of [6, 10], see also [9]. Since $u \in W_{l o c}^{1, q}(\Omega)$, the function $u$ is a weak solution of

$$
\begin{equation*}
-L u=\xi(x) \tag{2.1}
\end{equation*}
$$

with $\xi(x)=H(x, u, \nabla u)+h(x) \in L_{l o c}^{\frac{q}{2}}(\Omega)$, by $(H 1)$. By a standard $L^{p}$-regularity argument, see for example [17, Theorem 3.8], we deduce that $u \in W_{l o c}^{2, \frac{q}{2}}(\Omega)$. Now using Proposition 2.3 which is valid on any regular domain $\omega \subset \Omega$ it follows that

$$
u \in W_{l o c}^{1, t_{1}}(\Omega) \quad \text { where } \quad t_{1}=\frac{\frac{q}{2}(2-\alpha)-\alpha}{1-\alpha}>q
$$

If $t_{1} \geq N$ we are again done. Otherwise from (2.1) and the cited classical regularity argument, $u \in W_{l o c}^{2, \frac{t_{1}}{2}}(\Omega)$. Denoting

$$
\begin{equation*}
t_{n}=\frac{\frac{t_{n-1}}{2}(2-\alpha)-\alpha}{1-\alpha}>t_{n-1}>q>2 \tag{2.2}
\end{equation*}
$$

by a bootstrap argument we get $u \in W_{l o c}^{2, \frac{t_{n}}{2}}(\Omega)$ for all $n \in \mathbb{N}$ as long as $t_{n-1}<N$. We now claim that the increasing sequence $\left\{t_{n}\right\}$ exceeds the value $N$. Indeed, arguing by contradiction, if $t_{n}<N$ for every $n \in \mathbb{N}$, then the limit $l$ of $\left\{t_{n}\right\}$ has to be $l=2$. This contradicts that $t_{n}>q>2$. At this point the proof of the lemma is completed.

The motivation to observe that any solution of (1.1) has an additional regularity appears in the next comparison principle in $H^{1}(\Omega) \cap W_{\text {loc }}^{1, N}(\Omega) \cap \mathcal{C}(\bar{\Omega})$. Recall that $u_{1}$ is a lower solution of (1.1) if $u_{1}^{+} \in H_{0}^{1}(\Omega)$ and, for all $\varphi \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega)$ with $\varphi \geq 0$ a.e. $x \in \Omega$, we have

$$
\sum_{i, j=1}^{N} \int_{\Omega} a^{i j} \frac{\partial u_{1}}{\partial x_{i}} \frac{\partial \varphi}{\partial x_{j}} \leq \int_{\Omega} H\left(x, u_{1}, \nabla u_{1}\right) \varphi+\int_{\Omega} h \varphi .
$$

In the same way, $u_{2}$ is an upper solution of (1.1) if $u_{2}^{-} \in H_{0}^{1}(\Omega)$ and, for all $\varphi \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega)$ with $\varphi \geq 0$ a.e. $x \in \Omega$, we have

$$
\sum_{i, j=1}^{N} \int_{\Omega} a^{i j} \frac{\partial u_{2}}{\partial x_{i}} \frac{\partial \varphi}{\partial x_{j}} \geq \int_{\Omega} H\left(x, u_{2}, \nabla u_{2}\right) \varphi+\int_{\Omega} h \varphi
$$

Lemma 2.2. Assume that the hypotheses (L) and (H2) hold. Then if $u_{1}, u_{2} \in$ $H^{1}(\Omega) \cap W_{\text {loc }}^{1, N}(\Omega) \cap \mathcal{C}(\bar{\Omega})$ are respectively a lower solution and an upper solution of (1.1), then $u_{1} \leq u_{2}$ in $\Omega$.

Proof. Here we adapt an argument from [7], based in turn on an original idea from [8]. Consider the function $v=u_{1}-u_{2}$, which satisfies

$$
\begin{array}{cc}
-L v \leq H\left(x, u_{1}, \nabla u_{1}\right)-H\left(x, u_{2}, \nabla u_{2}\right), & \text { in } \Omega, \\
v \leq 0, & \text { on } \partial \Omega,  \tag{2.3}\\
v \in H^{1}(\Omega) \cap W_{l o c}^{1, N}(\Omega) \cap \mathcal{C}(\bar{\Omega}) . &
\end{array}
$$

For every $c \in \mathbb{R}$, let us consider the set $\Omega_{c}=\{x \in \Omega:|v(x)|=c\}$ and

$$
J=\left\{c \in \mathbb{R}: \operatorname{meas} \Omega_{c}>0\right\}
$$

As $|\Omega|$ is finite, $J$ is at most countable and, since for all $c \in \mathbb{R}, \nabla v=0$ a.e. on $\Omega_{c}$, we also have

$$
\begin{equation*}
\nabla v=0 \text { a.e. in } \bigcup_{c \in J} \Omega_{c} . \tag{2.4}
\end{equation*}
$$

Define $Z=\Omega \backslash \bigcup_{c \in J} \Omega_{c}$ and, for all $k \geq 0$, choose $\varphi=(v-k)^{+} \in H_{0}^{1}(\Omega) \cap L^{\infty}(\Omega)$ as test function in (2.3), to deduce by condition (L) that

$$
\eta\left\|\nabla(v-k)^{+}\right\|_{L^{2}(\Omega)}^{2} \leq \int_{\Omega}\left(H\left(x, u_{1}, \nabla u_{1}\right)-H\left(x, u_{2}, \nabla u_{2}\right)\right)(v-k)^{+} d x .
$$

Let $A_{k}=\{x \in \Omega: v(x) \geq k\}$. By (2.4), (H2) and $\left\|u_{1}\right\|_{\infty} \leq R,\left\|u_{2}\right\|_{\infty} \leq R$ for some $R>0$ we obtain a constant $M>0$ such that

$$
\begin{aligned}
\eta\left\|\nabla(v-k)^{+}\right\|_{L^{2}(\Omega)}^{2} & \leq \int_{A_{k}}\left(H\left(x, u_{1}, \nabla u_{1}\right)-H\left(x, u_{2}, \nabla u_{2}\right)\right)(v-k)^{+} d x \\
& \leq M \int_{A_{k} \cap Z}\left(\left|\nabla u_{1}\right|+\left|\nabla u_{2}\right|+b_{2}\right)|\nabla v|(v-k)^{+} d x \\
& =M \int_{A_{k} \cap Z}\left(\left|\nabla u_{1}\right|+\left|\nabla u_{2}\right|+b_{2}\right)\left|\nabla(v-k)^{+}\right|(v-k)^{+} d x .
\end{aligned}
$$

Since $v \in \mathcal{C}(\bar{\Omega})$ and $v \leq 0$ on $\partial \Omega$, we have that $(v-k)^{+}$has a compact support in $\Omega$, for all $k>0$, and hence $\left(\left|\nabla u_{1}\right|+\left|\nabla u_{2}\right|+b(x)\right) \in L^{N}\left(A_{k} \cap Z\right)$. This implies that

$$
\begin{align*}
\eta\left\|\nabla(v-k)^{+}\right\|_{L^{2}(\Omega)}^{2} & \leq M\left\|\left|\nabla u_{1}\right|+\left|\nabla u_{2}\right|+b\right\|_{L^{N}\left(A_{k} \cap Z\right)}\left\|\nabla(v-k)^{+}\right\|_{L^{2}(\Omega)}\left\|(v-k)^{+}\right\|_{L^{2^{*}}(\Omega)}  \tag{2.5}\\
& \leq \mathcal{S}_{N}^{-1} M\left\|\left|\nabla u_{1}\right|+\left|\nabla u_{2}\right|+b\right\|_{L^{N}\left(A_{k} \cap Z\right)}\left\|\nabla(v-k)^{+}\right\|_{L^{2}(\Omega)}^{2},
\end{align*}
$$

where $2^{*}=2 N /(N-2)$ and $\mathcal{S}_{N}$ denotes the Sobolev constant.
We want to prove that $v \leq 0$. Indeed, assume by contradiction that $v^{+} \not \equiv 0$ and consider the non-increasing function $F$ defined on $\left.] 0,\left\|v^{+}\right\|_{\infty}\right]$ by

$$
F(k)=\mathcal{S}_{N}^{-1} M\left\|\left|\nabla u_{1}\right|+\left|\nabla u_{2}\right|+b\right\|_{L^{N}\left(A_{k} \cap Z\right)}, \quad \forall 0<k<\left\|v^{+}\right\|_{\infty}
$$

and $F\left(\left\|v^{+}\right\|_{\infty}\right)=0$. By definition of $Z$ we have that $F$ is continuous and we can choose $0<k_{0}<\left\|v^{+}\right\|_{\infty}$ such that $F\left(k_{0}\right)<\eta$. By (2.5), $\eta\left\|\nabla\left(v-k_{0}\right)^{+}\right\|_{L^{2}(\Omega)}^{2} \leq$ $F\left(k_{0}\right)\left\|\nabla\left(v-k_{0}\right)^{+}\right\|_{L^{2}(\Omega)}^{2}$, which implies that $\left\|\nabla\left(v-k_{0}\right)^{+}\right\|_{L^{2}(\Omega)}=0$, i.e. $v \leq k_{0}<$
$\left\|v^{+}\right\|_{\infty}$, a contradiction proving that necessarily $v^{+}=0$ and hence $u_{1} \leq u_{2}$. This concludes the proof.

Proof of Theorem 1.1. Let $u_{1}$ and $u_{2}$ be two solutions of (1.1). By Lemma 2.1] we know that $u_{1}$ and $u_{2}$ belong to $\mathcal{C}(\bar{\Omega}) \cap W_{\text {loc }}^{1, N}(\Omega)$. Thus it follows from Lemma 2.2 that $u_{1}=u_{2}$.

Remark 2.1. In the proof of Theorem 1.1 the requirement that $\Omega$ satisfies condition (A) is used to show that any solution of (1.1) belongs to $\mathcal{C}(\bar{\Omega})$. In turn this property is used only in Lemma 2.2 to guarantee that for any solution $u$ of (1.1) the set $A_{k}=\{x \in \Omega: u(x) \geq k\}$ is compact for any $k>0$. It is an open question if the conclusion of Theorem 1.1 holds true without assumption (A).

As a corollary of Lemma 2.2 and Theorem 1.1 we obtain the following result which, under the condition (A), improves the results in [3, 4] concerning (1.1).

Corollary 2.1. Assume that $\Omega$ satisfies condition (A) and that condition ( $L$ ) holds. Let $H: \Omega \times \mathbb{R} \times \mathbb{R}^{N} \rightarrow \mathbb{R}$ be a Carathéodory function satisfying (H1) and such that, for a.e. $x \in \Omega, H(x, \cdot, \cdot) \in \mathcal{C}^{1}\left(\mathbb{R}^{N+1}\right)$ with

$$
\frac{\partial H}{\partial u}(x, u, \xi) \leq 0, \text { a.e. } x \in \Omega, \forall u \in \mathbb{R}, \forall \xi \in \mathbb{R}^{N}
$$

Assume moreover there exists a function $b_{3} \in L_{l o c}^{N}(\Omega)$ and a continuous nondecreasing function $C: \mathbb{R}^{+} \times \mathbb{R}^{+} \rightarrow \mathbb{R}^{+}$such that

$$
\left|\frac{\partial H}{\partial \xi}(x, u, \xi)\right| \leq C(|u|)\left(|\xi|+b_{3}(x)\right) \text {, a.e. } x \in \Omega, \forall u \in \mathbb{R}, \forall \xi \in \mathbb{R}^{N}
$$

If $u_{1}, u_{2} \in H^{1}(\Omega) \cap W_{\text {loc }}^{1, N}(\Omega) \cap \mathcal{C}(\bar{\Omega})$ are respectively a lower solution and an upper solution of (1.1), then $u_{1} \leq u_{2}$ in $\Omega$. In particular, (1.1) has at most one solution.

Proof. We just have to prove that (H2) holds. Let $x \in \Omega, u_{1}, u_{2} \in \mathbb{R}$ with $u_{1} \geq u_{2}$ and $\xi_{1}, \xi_{2} \in \mathbb{R}^{N}$. Define the function $F(t)=H\left(x, t u_{1}+(1-t) u_{2}, t \xi_{1}+(1-t) \xi_{2}\right)$,
for every $t \in[0,1]$. Observe that $F \in \mathcal{C}^{1}(\mathbb{R})$. Moreover we have

$$
\begin{aligned}
H\left(x, u_{1}, \xi_{1}\right)- & H\left(x, u_{2}, \xi_{2}\right)=F(1)-F(0) \\
= & \int_{0}^{1} \frac{d}{d t} F(t) d t \\
= & \int_{0}^{1} \frac{\partial H}{\partial u}\left(x, t u_{1}+(1-t) u_{2}, t \xi_{1}+(1-t) \xi_{2}\right) d t\left(u_{1}-u_{2}\right) \\
& +\int_{0}^{1} \frac{\partial H}{\partial \xi}\left(x, t u_{1}+(1-t) u_{2}, t \xi_{1}+(1-t) \xi_{2}\right) \cdot\left(\xi_{1}-\xi_{2}\right) d t \\
\leq & \int_{0}^{1}\left|\frac{\partial H}{\partial \xi}\left(x, t u_{1}+(1-t) u_{2}, t \xi_{1}+(1-t) \xi_{2}\right)\right| d t\left|\xi_{1}-\xi_{2}\right| \\
\leq & \int_{0}^{1} C_{0}\left(\left|t u_{1}+(1-t) u_{2}\right|\right)\left[\left|t \xi_{1}+(1-t) \xi_{2}\right|+b_{3}(x)\right] d t\left|\xi_{1}-\xi_{2}\right| \\
\leq & C_{0}\left(\left|u_{1}\right|+\left|u_{2}\right|\right)\left[\left|\xi_{1}\right|+\left|\xi_{2}\right|+b_{3}(x)\right]\left|\xi_{1}-\xi_{2}\right| .
\end{aligned}
$$

This proves that (H2) is valid and we can apply Lemma 2.2 and Theorem 1.1 to conclude.

## Appendix A. Sufficient conditions for condition (A)

We prove in this section that $\Omega$ satisfies condition (A) whenever $\partial \Omega$ is Lipschitz. Recall that, by [12, Theorem 1.2.2.2], $\partial \Omega$ is Lipschitz if and only if the uniform cone condition is satisfied.

Definition A.1. ([12, Definition 1.2 .2 .1, p.10]) Let $\Omega$ be an open subset of $\mathbb{R}^{N}$. We say that $\Omega$ satisfies the uniform cone property if, for every $x \in \partial \Omega$, there exists a neighbourhood $V$ of $x$ in $\mathbb{R}^{N}$ and new coordinates $\left\{y_{1}, \ldots, y_{N}\right\}$ such that (a) $V$ is a hypercube in the new coordinates, i.e.,

$$
V=\left\{\left(y_{1}, \ldots, y_{N}\right) \in \mathbb{R}^{N} \mid-a_{i}<y_{i}<a_{i}, 1 \leq i \leq N\right\}
$$

for some $a_{i}>0, i=1,2, \ldots, N$;
(b) $y-z \in \Omega$ whenever $y \in \bar{\Omega} \cap V$ and $z \in C$, where $C$ is the open cone $\left\{z=\left(z^{\prime}, z_{n}\right)|(\cot \theta)| z^{\prime} \mid<z_{n}<h\right\}$ for some $\left.\left.\theta \in\right] 0, \pi / 2\right]$ and some $h>0$.
Lemma A.1. Let $\Omega \subset \mathbb{R}^{N}$ be a bounded domain. If $\partial \Omega$ is Lipschitz, then $\Omega$ satisfies the condition (A).

Proof. As it has been mentioned we can assume that $\partial \Omega$ satisfies the uniform cone condition. Arguing as in the proof of [12, Theorem 1.2.2.2], we know that $\{x\}-C \subset \Omega$ but we can also observe that $\{x\}+C \subset \Omega^{c}$, at least if the distance from $x$ to $V^{c}$ is greater that $h / \cos \theta$; this last condition can always be achieved by choosing a smaller $h$. Indeed, if $(\{x\}+C) \cap \bar{\Omega}$ is not empty, let $y$ be a point in the intersection. Then $y \in \bar{\Omega} \cap V$ since $\left|y_{n}-x_{n}\right|<h$ and consequently, $\{y\}-C \subset \Omega$, but this contradicts the fact that $x \in\{y\}-C$.

For every $r>0$, we have that $\Omega \cap B_{r}(x) \subset B_{r}(x) \backslash\left(B_{r}(x) \cap(\{x\}+C)\right)$ and hence

$$
\begin{aligned}
\operatorname{meas}\left(\Omega \cap B_{r}(x)\right) & \leq \operatorname{meas} B_{r}(x)-\operatorname{meas}\left(B_{r}(x) \cap(\{x\}+C)\right) \\
& =\operatorname{meas} B_{r}(x)\left(1-\frac{\operatorname{meas}\left(B_{r}(x) \cap(\{x\}+C)\right)}{\operatorname{meas} B_{r}(x)}\right) \\
& =\operatorname{meas}\left(B_{r}(0) \cap C\right) .
\end{aligned}
$$

If $r \leq h$, the cone $C(\theta, r \cos \theta)$ of vertex 0 , opening angle $\theta$ and height $r \cos \theta$ satisfies

$$
C(\theta, r \cos \alpha) \subset\left(B_{r}(0) \cap C\right) .
$$

Hence,

$$
\frac{1}{N+1}\left(\operatorname{meas}_{\mathbb{R}^{N-1}} B_{\mathbb{R}^{N-1}}(r \sin \theta)\right) r \cos \theta \leq \operatorname{meas}\left(B_{r}(0) \cap C\right)
$$

and therefore

$$
\begin{aligned}
\operatorname{meas}\left(\Omega \cap B_{r}(x)\right) & \leq \text { meas } B_{r}(x)\left(1-\frac{\operatorname{meas}\left(B_{r}(0) \cap C\right)}{\operatorname{meas} B_{r}(0)}\right) \\
& \leq \text { meas } B_{r}(x)\left(1-\frac{\frac{1}{N+1} \frac{\pi^{(N-1) / 2}}{\Gamma\left(\frac{N-1}{2}+1\right)}(r \sin \theta)^{N-1} r \cos \theta}{\frac{\pi^{N / 2}}{\Gamma\left(\frac{N}{2}+1\right)} r^{N}}\right) \\
& =\text { meas } B_{r}(x)\left(1-\frac{\Gamma\left(\frac{N}{2}+1\right)(\sin \theta)^{N-1} \cos \theta}{(N+1) \pi^{1 / 2} \Gamma\left(\frac{N-1}{2}+1\right)}\right)
\end{aligned}
$$

i.e., condition (A) holds with $r_{0}=h$ and $\theta_{0}=\frac{\Gamma\left(\frac{N}{2}+1\right)(\sin \theta)^{N-1} \cos \theta}{(N+1) \pi^{1 / 2} \Gamma\left(\frac{N-1}{2}+1\right)}$.
